TAYLOR'S

GENERAL CATALOGUE OF STARS

FOR THE EQUINOX 1835·0

FROM OBSERVATIONS

MADE AT THE

MADRAS OBSERVATORY

DURING THE YEARS

1831 to 1842.

REVISED AND EDITED BY

A. M. W. DOWNING, M.A., D.Sc., F.R.S.,  
SUPERINTENDENT OF THE NAUTICAL ALMANAC.

MADRAS  
GENERAL CATALOGUE OF STARS  
FOR  
1835·0.

---

INTRODUCTION.

This Catalogue contains the results of observations of Stars made at the Madras Observatory during the years 1831 to 1842 inclusive, under the direction of the late Thomas Glanville Taylor. The Catalogue places represent the mean Right Ascensions and Declinations of the Stars at the mean epoch of observation, reduced without proper motion to the Equinox of 1835·0.

*The Right Ascensions.*

The Transit Instrument is described in detail in Vol. I. of the Madras Observations. Here it is sufficient to state that the focal length of the telescope is 61 inches, and the clear aperture  $3\frac{3}{4}$  inches, and that a power of 150 was employed. The transits were observed over five fixed vertical wires. Much trouble was caused in the early years of Taylor's term of office by the unequal wear of the pivots; and corrections on this account, of a more or less problematical character, have been applied to the observations (Vol. II., page 8). At the end of 1833, however, the pivots were fitted with collars of steel, and since that time no further evidence of wear was detected.

The Error of Level was determined by a spirit-level, and it has not appeared necessary to revise the Level Errors as adopted in the original reductions.

The revision of a Catalogue of 11,000 Stars is a work of such magnitude that it was necessary to exercise the utmost vigilance in order to keep the expenses within reasonable limits; otherwise there would have been a danger of the work being left in an unfinished state. Hence the necessity of utilising, as far as possible, the existing material.

The Error of Collimation was determined from the observation of the (known) angular distance between the North and South Meridian Marks. From the beginning of 1840 onwards, owing to the obliteration of the South Mark, and the dilapidated state of the Micrometer-screw, the practice was adopted of inverting the instrument on the North Mark, and adjusting it so that the error of Collimation should be zero. The observations made during the last three years are comparatively very few, and it did not appear necessary to revise the determinations of Collimation error (except in some isolated cases), although during the years referred to they were made in this unsatisfactory way.

The Error of Azimuth was determined from observations of the Meridian Marks, the positions of which were assumed from observations of close polar stars, mainly of Polaris, above and below the pole. The determination of Azimuth Error presents certain difficulties in a low latitude such as that of Madras, a circumstance which must give rise to some uncertainty in the concluded Right Ascensions of stars of high declination. After some consideration, I decided to follow Taylor's methods, as the observations did not lend themselves to a revision of these, and Taylor appears to have exercised the greatest care and vigilance in all matters relating to the adjustment of the instruments. But I have been careful to attend to such details as the changes in the positions of the Marks, referred to in Vol. II., page cxxxii, and the error in the assumed position of the North Mark, referred to in Vol. VII., page (xiii). Attention to these and similar points has occasionally (especially during periods when Taylor was absent from the Observatory) necessitated the application of comparatively large corrections to the Azimuth Errors originally adopted. That some further correction for Azimuth Error of the Transit is required appears probable from the comparison with Newcomb's Catalogue of Fundamental Stars given below. But I preferred to leave the results as they were rather than to apply a correction of an *a posteriori* character.

The Concluded Right Ascensions of Polaris, observed above and below the pole, and reduced to 1835·0, are as follows:—

	h	m	s.	
Polaris, . . . . .	1	0	49·07	(89 observations).
Polaris S.P., . . . . .	1	0	49·71	(100 observations).

The Transit Clock used in the observations was one by Shelton, with a common dead-beat escapement and gridiron pendulum. It had, apparently, no maintaining power, and the effect of the periodical winding of the clock on its going often gave rise to considerable difficulty in determining the rate.

The Clock Errors were determined from the adopted positions of Standard Stars taken from Auwers' Fundamental Catalogue (*Publication der Astron. Gesellschaft*, XIV. and XVII.), excluding stars north of  $+70^\circ$  Dec. The stars used for determination of clock error were not usually kept for place on any day on which the observations did not extend over six hours at least, or on which there were fewer than six Clock Stars observed by the same observer. On account of the somewhat unsatisfactory character of the Collimation and Azimuth determinations during 1840-42, alluded to above, no observations of Clock Stars, and no observations of close Polar Stars (except  $\lambda$  Ursæ Minoris) made during these years have been included in the Catalogue.

The probable error of a single determination of Right Ascension, estimated by the discordance of each day's result from the annual mean, for several stars near the zenith, and therefore not far from the equator, is

$$\pm 0.081.$$

### *The Declinations.*

The Mural Circle is described in detail in Vol. I. of the Madras Observations. The Circle is 48 inches in diameter, and is provided with a telescope of 49 inches focal length, with object-glass of  $3\frac{3}{4}$  inches aperture. A power of 120 was employed throughout. The circle is divided to every  $5'$ , and was read by four microscope-micrometers. In the observations of stars a fixed horizontal wire in the eye-piece was used.

No observations of Runs of the microscope-micrometers appear to have been recorded, except during the years 1840-42. Taylor, however, remarks that the microscopes were kept in adjustment so that the Runs—which were examined once a week—should be of small amount, and no correction for Runs was applied in the original reduction of the observations. It did not appear advisable to make a change in this respect towards the end of the period over which the observations extend, and accordingly I have not introduced a correction for Runs into the revised reduction of the Circle observations made during 1840-42.

The Division Errors applied to each circle observation are taken from the Table in the Madras Observations, Vol. V., pages ccxvii, ccxviii. It should be noted that Taylor was at first unaware of the magnitude of the division errors of the Madras Circle, which were assumed to be negligible, and it was not until late in 1839 that a complete investigation was undertaken. The observations made up to that time were then corrected by assuming that the adopted Index Errors would be affected by a constant error corresponding to the mean of the errors of every division of the circle, and then applying to each circle-reading the difference between this mean and its proper division error. The difference of the results derived in this way from the revised results is often considerable.

The Refractions used in the original reductions were those of Atkinson, published in Vol. II. of the *Memoirs* of the Royal Astronomical Society. To these I have applied systematic corrections taken from an extension of the Table in the Madras Observations, Vol. V., pages 2, 3, to reduce them to the refractions of Bessel's *Tabulæ Regiomontanæ*. For a few very low stars the refractions have been computed directly from the *Tabulæ*.

The Index Errors were determined from the adopted positions of Standard Stars taken from Auwers' Fundamental Catalogue (*Publication der Astron. Gesellschaft*, XIV.), between declinations  $+55^\circ$  and  $-10^\circ$ , the positions being corrected by the quantities given on page 12 of *Publication* XIV., which reduce the places of the Fundamental Catalogue, sensibly, to those of Auwers' Mean System (*Ast. Nach.*, No. 1536). The attempt to determine an independent system of declinations by means of the "Reflecting Collimator" was abandoned for the reasons given in *Monthly Notices* of the Royal Astronomical Society, Vol. LVII., page 409.

Taylor appears to have made only two determinations of flexure during the period 1831-1842. One, made in 1835, gave a negative flexure of  $0''.19$ ; the other, made in 1836, gave a positive flexure of  $0''.56$ . It has not been possible, therefore, to apply any correction for flexure to the observations.

The Concluded Declinations of Polaris, observed above and below the pole, reduced to 1835.0, are as follows:—

			°	'	"
Polaris, .. . . .	+88	25	47.44	(13 observations).	
Polaris S. P., . . . .	+88	25	44.88	(11 observations).	

The probable error of a single determination of Declination, estimated by the discordance of each day's result from the annual mean, for several stars near the zenith, is

$$\pm 0.60.$$

At a zenith distance of  $65^\circ$  this probable error is increased to

$$\pm 0.87.$$

The observed Right Ascensions and Declinations of Standard Stars were reduced to mean places for the beginning of the year of observation by the help of the Pulkowa "Tabulæ quantitatum Besselianarum pro annis 1750-1864." For other stars the appropriate corrections applicable to Taylor's Star Corrections to reduce them to Star Corrections deduced from the Struve-Peters' Constants were taken from specially constructed Tables.

The mean Right Ascensions and Declinations for the beginning of each year of observation were reduced to the Equinox of 1835.0 by the application of the precessions printed in the Catalogue; the Secular Variations of the precessions being allowed for whenever sensible.

*Explanation of the Separate Columns of the Catalogue.*

"No." is the rotation number.

"Taylor's No." is the number attached to the star in the original Catalogue. This series of numbers tends to differ from that in the first column mainly because Taylor affixed numbers to several stars that he did not observe. Also, in some cases, different numbers were assigned to objects that the revision has shown to be really the same star.

"Star's Name." In those cases where the name of the Constellation, with letter or number, is given, the adopted nomenclature is that of the British Association Catalogue of Stars, except in four instances (Nos. 915, 1077, 5266, and 9448), for which the nomenclature of Auwers' Bradley is preferred. Other stars are designated by the number in Auwers' Bradley, in Lacaille's Catalogue of 9766 Stars, by the hour and number in Piazzi's Catalogue, by the number in Brisbane's Paramatta Catalogue, in Gould's Catalogo General, in Stone's Cape Catalogue for 1880.0, in the B.D. Zones, in the C.P.D. Zones, in B.A.C., or, in cases where the star cannot be identified, in Taylor's original Catalogue.

"Magnitude." The value set down is the mean between the estimations made with the Transit, and with the Circle. The value 2.3 (*exempli gratia*) implies that in brightness the star is between the second and third magnitudes. The estimations appear to be very rough, and no reliance should be placed on them as affording evidence of variability.

"Mean R.A., 1835.0." These results refer to the mean epoch of observation and Equinox of 1835.0.

"Mean Date." The mean epoch of observation in R.A. expressed in years from 1800.

"No. of Obs." The number of Observations in Right Ascension.

"Annual Precession, 1835·0." The corrections to Taylor's precessions in R.A., as printed in the original Catalogue, to reduce them to precessions corresponding to the Struve-Peters' Constants, were computed from the expression

$$+0\cdot0007+0\cdot000025 \times \text{Taylor's Precession.}$$

For stars of higher declination than  $80^\circ$  the precessions were computed directly from the expression

$$3\cdot0715+1\cdot3372 \sin \alpha \tan \delta.$$

"Mean Dec., 1835·0." These results refer to the mean epoch of observation and the Equinox of 1835·0.

"Mean Date." The mean epoch of observation in Declination expressed in years from 1800.

"No. of Obs." The number of Observations in Declination.

"Annual Precession, 1835·0." The corrections to Taylor's precessions in Declination to reduce them to precessions corresponding to the Struve-Peters' Constants, are given by the expression

$$+0\cdot0005 \cos \alpha.$$

This quantity was considered negligible, and, except in cases where the R.A. of the star was sufficiently altered by the revision to necessitate a re-computation of the precession, or where there was reason to think that the original value was erroneous, Taylor's precession was adopted unaltered. In the exceptional cases referred to, the precessions were computed directly from the expression

$$20\cdot0577 \cos \alpha.$$

"Bradley." The reference gives the number of the Star in Auwers' Bradley.

"Lacaille." The reference gives the number of the Star in Lacaille's Catalogue of 9766 Stars.

"Piazzi." The reference gives the number of the Star for the current hour of R.A. in Piazzi's Catalogue.

Every effort has been made to detect mistakes of arithmetic in the original reductions—of which a large number have been found—and to guard against their introduction into the revised results. But a somewhat extensive experience of numerical work has convinced me that it is idle to expect complete immunity from error in a mass of computations such as it has been necessary to undertake, and I can only hope that no very serious errors have escaped detection.

My examination of the Madras Observations, made under his direction, has led me to form a very high opinion of Taylor, and of the work which he accomplished in the face of enormous difficulties. That his work may now be rendered more useful to astronomers is the reward for which I hope in the publication of this revised edition.

The great mass of the computations has been undertaken by Mr Jackman and Mr Sprigge, Assistants in this Office. By far the larger share has fallen to Mr Sprigge, who has also undertaken the preparation of the copy for press, and the reading of the proof-sheets, a part of the work on which he has bestowed great care and attention. My acknowledgments are due to the authorities of the India Office for the loan of the books of original reductions, which had been deposited, for safe keeping, in the Record Room of the Greenwich Observatory. The expenses of the calculations involved in the preparation of the work have been met by a succession of grants made to me by the Government Grant Committee of the Royal Society. The cost of printing has been defrayed partly by a grant from the India Office, and partly by a grant from the Publication Fund of the Royal Society. My acknowledgments are due to the various bodies concerned for the assistance thus rendered.

A. M. W. DOWNING.
